

## **Fred Hoyle on the Boil**

Eminent 20th Century Scientist Fred Hoyle gave a very useful lesson about prediction in science. An astronomer produced a mathematical formula that accurately predicted the number of sunspots over the whole of a century. But the formula failed completely when new data came in. Hoyle concluded that it is easy to find a formula that fits the data, but difficult to invent one that predicts future events.

The entire global warming scam and associated zeal to tax the inhabitants of the planet are based on the IPCC's computer models predicting future events.

It is embarrassing for the IPCC, but English scientist Christopher Monckton and many others, have shown their models do not and cannot represent the real world in which we live.

The IPCC climate models require temperatures in the troposphere in the tropical regions to rise as concentrations of carbon dioxide increase. But more than a decade of close observation with weather balloons and satellite observations have failed to find any temperature rise. Not any.

The outputs from the IPCC's computer models are not worth the paper on which they are printed.

The highly complex simulations of the atmosphere which has taken the IPCC's mathematicians years to construct are worthless against the much more complex real world atmosphere, driven by the unpredictable activities of the sun. Activities that are so complex that nobody anywhere has yet been able to record, describe or predict.

Again Fred Hoyle assists us to recognise the Kafkaesque climate policy of Rudd's Government.
